

Executive Summary: Retail Sales Analysis

This project analyses retail sales data to identify key revenue drivers, customer behaviour patterns, and operational inefficiencies. The dataset includes transaction-level details such as product categories, customer demographics (age and gender), payment methods, store types, and delivery status.

The analysis reveals that a small proportion of high-value orders contributes significantly to overall revenue, highlighting the importance of focusing on premium customer segments. Certain product categories and cities consistently outperform others, indicating strong opportunities for targeted marketing and regional expansion.

Customer demographics show clear variations in purchasing behaviour. Differences in spending patterns across age groups and gender segments suggest that personalised marketing strategies can significantly enhance customer engagement and sales performance.

Operational analysis indicates that delivery performance plays a crucial role in revenue realisation. Failed or delayed deliveries not only lead to revenue loss but also negatively impact customer satisfaction and brand trust.

Based on these insights, the following strategic recommendations are proposed:

- Focus on high-performing product categories to maximise revenue generation
- Implement loyalty programs to retain high-value customers
- Optimise logistics and supply chain processes to reduce delivery failures
- Use demographic insights to design targeted and personalised marketing campaigns
- Expand operations and marketing efforts in top-performing cities

By implementing these strategies, the business can improve revenue growth, enhance customer retention, and achieve greater operational efficiency.
